Ten Best Readings Relating to Hepatic Metastases

Mokenge Malafa, MD, FACP

From the Gastrointestinal Tumor Program at the H. Lee Moffitt Cancer Center & Research Institute, Tampa, Florida.

This decision model identifies individual patient resectability, recommending optimal treatment strategies. It can also be used for medical education.

This review summarizes the current data on neoadjuvant chemotherapy, the rationale for this approach, potential complications, and future prospects.

This randomized study compared hepatic arterial infusion with fluorouridine and dexamethasone plus systemic fluorouracil, with or without leucovorin (combined therapy) and systemic therapy alone, consisting of fluorouracil with or without leucovorin (monotherapy). There was improved progression-free survival and survival free of hepatic progression, as well as a trend toward improved long-term outcome in the group receiving combined therapy, with a survival rate of approximately 40% at 10 years, even among patients with the greatest risk of recurrence.

This review describes the current data on HAI for colorectal cancer and includes an assessment of new chemotherapeutic agents delivered via HAI, neoadjuvant HAI, HAI combined with systemic chemotherapy, and HAI for early-stage colorectal cancer. Continued progress in the field of HAI therapy may reduce the morbidity and mortality associated with CRC.

Hepatic resection is the treatment of choice for colorectal liver metastases. Radiofrequency ablation alone or in combination with resection for unresectable patients does not provide survival comparable to resection, and it provides survival only slightly superior to nonsurgical treatment.

The data on genes associated with metastasis should contribute to a better understanding of the progression of colorectal tumors and facilitate prediction of their metastatic potential.

Whole-body FDG-PET may identify unrecognized extrahepatic metastases in patients with potentially resectable liver metastases imaged by computed tomography. However, additional information provided by PET is not as reliable as suggested by earlier retrospective studies.

PET for diagnosis and staging does not generate additional survival effectiveness compared with computed tomography alone. However, cost savings associated with its use and the improvement of therapeutic management justify its generalization in clinical practice.

This consensus report gives a detailed description
of the use of somatostatin analogs in the management of neuroendocrine tumors of the gastroenteropancreatic system. The efficacy of octreotide and lanreotide in reducing diarrhea and flushing is described, and practical information on somatostatin analog treatment is provided.

This article reviews development of innovative multidisciplinary modalities and the aggressive surgical approach that has been adopted to extend the frontiers of surgical therapy for colorectal hepatic metastases.

The next issue of Cancer Control will focus on thyroid cancer. Among the topics reviewed will be poorly differentiated and anaplastic thyroid cancer, familial nonmedullary thyroid carcinoma, thyroid nodule workup and diagnosis, well-differentiated thyroid cancer, and genetic aberrations in thyroid carcinoma.
